

API Architecture

The overall architecture consists of the following main components:

- **Client (Player Frontend)** – web or mobile client, opens game lobby and game URLs.
- **Operator Platform (Optimo)** – owns player accounts, wallets, sessions, KYC, limits.
- **Game Aggregator (Integration Service)** – unified API layer for launching games and routing wallet calls.
- **Game Operators / RGS** – individual game servers responsible for game logic and RNG.

Main Flows

1. Player opens lobby / selects game -> request goes to Operator.
2. Operator calls Game Aggregator **Game Launch API** to obtain game URL.
3. Player is redirected (or iframe-loaded) to Aggregator / Operator game client.
4. During gameplay, Operator (via Aggregator) calls **Operator Wallet Callbacks** (`/balance`, `/bet`, `/win`, `/rollback`).
5. Operator responds with updated balance and transaction identifiers.

Idempotency and Duplicate Request Handling

All Seamless Wallet operations (`bet`, `win`, `rollback`) are **idempotent**.

The Operator must guarantee that:

- `transaction_id` is unique per (`operator` + `game_id`).
- Processing the same `transaction_id` multiple times returns the **exact same response** as the original request.
- **No additional balance changes** are applied for duplicate calls.

**Note**

This ensures that retries due to network errors do not affect financial correctness.
